Tactix: H2 Unit-Publication Controls

Report to Andrew

25 September 2026

Outcome

The new 16-clause, one-retained-reason H2 reproducer rules out another simple no-option DSR repair. Nine pinned checker-only variants tested publishing implied unit 19, publishing the local 18/19 closure, omitting the reason-clause deletion, and repeating that deletion. None verified under the frozen canonical no-option `dsr-trim`; all outcomes and raw logs are preserved in AM437. No solver, proof emitter, checker binary or acceptance route changed.

What the result means

The exact ASCII re-encoding reproduces the binary baseline's backward watch-pointer failure and forward SR-obligation failure. Publishing unit 19 before deleting input clause 15 can make that deletion effective in the checker: a second identical deletion then fails because there is no matching clause. But the explicit unit remains in the checked formula, and a later SR witness still fails against a different clause obligation. Omitting the deletion also leaves the baseline failure. Thus neither clause-population alignment by one publication nor this local closure is a complete proof derivation. These controls corroborate the earlier original-H2 results; they do not establish that the canonical contract is impossible in general.

The diagnostic `-delete-implied-units` contract verifies this H2 proof through Trestle, yet archived real-solver controls show it can also reject proofs accepted by the no-option contract. It is not a monotone relaxation. A production switch would require an explicit contract decision and broad positive/negative, original-CNF and cumulative gate revalidation. That choice has been put to the user; the no-option route remains canonical until decided.

Next work

Design a checker-visible proof-state model or independent SR derivation that works across retained reasons and interleaved deletions without masking a public action. The current-source full Debug job `1723391` and paired AES extended-checker tasks `1723443` remain running on frozen pins. H2/N2, universal N1, N3/N4 and the retained Rank/B+C/WV gates remain open. The previously identified policy-layer refactors still precede production online learning, and the requested 5,000-second full Tier-D comparison remains post-goal.
