Tactix: Sweep Scheduling-Parity Audit Update

Report to Andrew

25 September 2026

Outcome

A current-source review found that two Sweep N4 ledger rows had retained historical "isolated, unpromoted" wording after their implementations entered production in the September 12 online-strategy refactor. The current code does run the embedded solver for live empty and one-clause environments, and it revalidates retained Sweep seeds once at call entry. I corrected the living ledger and engineering notes; no solver behavior or checker route changed.

Evidence and remaining work

The focused `sweep_small_env` and `sweep_retained` tests pass on the latest Release and ASan+UBSan builds. They cover initial solve/model and effort on small environments, as well as retained front/tail eligibility, occurrence bounds and the no-recheck-at-pop boundary. Source blame and test history attribute both production paths to commit `7a668e76`. The technical report lists the exact code paths and gate limits. Documentation size, references, inventory, option coverage and rule/policy checks pass.

"Implemented" is not "N4 accepted." The small-environment row still needs current-source cumulative Rank/B28+C5 performance and affected-scope fuzz. The retained-entry row also lacks complete reference parity for its incomplete/fresh-admission/completion lifecycle. Historical isolated native trace and timing cannot be transferred silently to the combined candidate. The AM401, AM412 and AM414 fuzz owners remain active; the H2 no-option DSR proof rejection and the broader N1–N4 gates remain open. The full post-goal 5,000-second Tier-D comparison has not been submitted.

Next action

Consume terminal owner reports on their immutable pins, resolve the H2 proof contract, then test the remaining Sweep lifecycle and cumulative gates on a single correctness-clean candidate. Production online learning still needs the shared default-exact slot controller and owned safe-point strategy switches described in the earlier readiness audit.
