Tactix: removal of the MAB integration

Codex for Andrew

27 September 2026, 23:53 UTC

Outcome and decision. The user directed us to purge MAB from Tactix. The production two-arm EVSIDS/CHB implementation, restart rewards, search-progress admission, configuration and CLI controls, statistics, and dedicated tests have been removed. Stable search now uses EVSIDS. Later independent proof, API, preprocessing and performance fixes remain; in particular the post-MAB late Factor activation-order fix was preserved when restoring the heuristic code. Frozen AE-Kissat-MAB source and benchmark data remain reference evidence, not an active Tactix strategy.

The frozen Tier D cross-binary reference solves 875/1,166 instances for AE-Kissat-MAB versus 881/1,166 for Kissat 4.0.4 under the same 5,000-second, four-CPU, 32-GiB limits. This does not isolate MAB's causal effect, but it gives no basis for keeping a costly default integration. A four-row immediate-MAB diagnostic verified two SAT models in 70.474 and 195.117 seconds and timed out twice at 600 seconds. The wider AM517 diagnostic was canceled by user direction; partial results were retained.

Validation and limits. Fresh Debug and Release builds succeed. Fourteen focused Release tests pass, including strategy, scheduling, restart, public API, random-policy and proof checks. The Debug sweep has passed 186/187 selected tests with the long `lucky` case still running at this report time; a prior Debug gate took 1,606.58 seconds for that case. The stale P4 fixture was updated to pass the already-required `dsr-trestle` route to the checker; the checker contract itself did not change. Documentation and config checks pass. Tiny SAT and UNSAT formulas return the same verdicts with and without proof output, and the automatic UNSAT proof independently verifies through its declared `dsr-cake_lpr` route. These checks establish bounded functionality, not performance or full N1–N4 acceptance.

Gate state and next actions. Old-pin WV100 has 99/100 valid final rows; its final `ncc` checker and dependent scorer are pending. Old-pin WV2 has already failed coverage on ten 600-second solver timeouts; one large UNSAT checker and its scorer remain active. Old-pin full Debug is also still running. Those outcomes belong to source `0a906338`, before this purge, and cannot certify the new pin. Next we will consume their terminal records, complete the new Debug check, then rerun affected independent proof/model, fuzz and performance gates on an immutable no-MAB pin. Public D2F reach and the user's overall-performance threshold remain open. The learning-readiness review and full 1,166-instance Tier D production run remain gated on verified N1–N4; no Tier D submission has occurred.

Evidence. `benchmarks/reports/2026-09-27-am518-mab-purge-checkpoint.md`; `benchmarks/reports/2026-09-27-am514-wv2-current-pin-performance-gap.md`; `benchmarks/reports/2026-09-27-am516-immediate-mab-cdcl-screen-terminal.md`; `benchmarks/baselines/sc24-26-32g-5000s/results.json`.
