Tactix: Current-Source H2 Proof-Contract Decision

Report to Andrew

25 September 2026

Outcome

I replayed the exact 21-variable H2 public-API action program against the latest Release solver objects. The binary native-DSR certificate is byte-identical to the historical parent proof. With the canonical no-option `dsr-trim` command, both backward and forward checking reject it. With the same pinned binary's diagnostic `-delete-implied-units` option, both directions verify and both decoded LSR elaborations pass independent Trestle. No production route or solver rule was changed.

Evidence and interpretation

The exact run is hwulab job 1722271 (two CPUs, 8 GiB; one second), archived with its driver, hashes, proof and checker logs in the AM423 probe. The technical report records each status and the proof hash. In no-option mode the checker retains six requested deletions because their clauses are current global unit-propagation reasons after an explicit root unit. Its later direct-SR witness is therefore checked against a larger clause population than the solver's. This explains the specific replay; it is not proof of a general repair algorithm. A fixed deletion reorder or suppressing a legal public action would not meet the project's generality and N1 requirements.

Seven current Release N1 fixtures passed, including representative public rule instances, online composition, policy-independent Sweep/Reduce reach, and Decide. They do not prove universal N1. The AM401, AM412, and AM414 Claude-owned counted campaigns remain active on immutable older pins; their results cannot be transferred to this source. No performance claim is made.

Decision and next work

The canonical proof contract needs a deliberate choice. Preserving the no-option route requires a checker-visible proof-state/emission design for implied-unit-reason deletions that also preserves every legal action. Permitting `-delete-implied-units` requires changing the calculus/oracle contract, replacing contract-specific negative controls, broad original-CNF proof and model fuzz, and rerunning the retained gates; the option is not a monotone relaxation. I requested that choice and have kept the no-option route pending an answer. H2 and combined N1–N4 remain unverified. The requested full 5,000-second Tier-D run (four CPUs, 32 GiB, hwulab) remains downstream of those gates; none was submitted.
