Tactix: WV2–89 current-route launch and gate status

Codex for Andrew

27 September 2026, 23:07 UTC

Outcome. The user directed us to proceed assuming the remaining WV100 proof check will pass. This authorizes the next gate but does not certify that proof. We submitted the frozen current-source WV2–89 array `1731864_0-88` on `cpu-dense-hwulab-q`. At 23:07 UTC, 74/89 final rows were valid: 48 original-CNF SAT models and 26 complete independent UNSAT proof routes. No wrong verdict, bad certificate, or cleanup failure was observed in these final rows. The other 15 rows are in progress. The accepted WV2–89 gate remains 89/89 within 600 solver seconds and 32 GiB per row.

Frozen route and reporting correction. The array uses solver source `0a906338` and Release binary SHA-256 `cab44387ea47f3ed5d74cbf1a9bb702f321cf9164a3df791ef4b07d760c08656`. Each task has 12 CPUs, 32 GiB, 600 seconds for solving, and 57,600 seconds for independent checking. There is no throttle, node constraint, or checker override. Native DSR first passes no-option `dsr-trim`; the solver's declared route chooses CakeLPR or Trestle. SAT models are checked against the original CNF. Manifest, matrix, all 89 inputs, solver, runner, and checkers are hashed. The dependent scorer runs only after the full array is terminal.

The frozen WV2 scorer validates all 89 records but mistakenly prints `checked_clean: 100`. The first pending scorer `1731931` was canceled before execution. Its replacement `1731971` runs that unchanged pinned scorer, asserts the required 57 SAT plus 32 UNSAT checks and the known display typo, then publishes `checked_clean: 89` while retaining the raw value and explicit correction in its JSON. This fixes only the reported count; no gate, checker contract, solver, or frozen manifest changed.

Other validation. The WV100 array `1731686_0-99` has 99/100 valid final rows: all 33 SAT models and 66 UNSAT proofs are independently checked. The remaining `ncc_none_21015` proof checker is running on a current-source proof whose SHA differs from the archived slow certificate. Dependent scorer `1731826` awaits it. Current-route full Debug job `1731798` has 187/188 passing tests; the long scripted-default demonstration is still running. The earlier pre-route Debug suite passed 188/188 but is not a substitute. The repaired-source Phase 1 Rank 50/50 and B28+C5 33/33 are independently checked at 7,553.134 and 905.892 solver seconds. These totals meet even their original targets; the user accepted 5% aggregate leeway.

Open decisions and next work. The user parked the full Debug/fuzz/public-D2F acceptance item pending questions. A proposed replacement for the old per-tier performance and N4 ledger criterion awaits a precise overall-performance threshold. Neither is silently counted as passed. The next action is to consume terminal WV2, WV100, scorer and Debug records, diagnose any 600-second or checker failure as a general rule/strategy issue, and rerun only affected gates on a new immutable pin. The public D2F boundary and complete N1–N4 verification remain open. The

online-learning readiness review is due after the agreed gates; production learning has unresolved inprocessing slot ownership and switchable branching/deletion handles. No full 1,166-instance Tier D campaign has been submitted.
