Tactix interim audit: shipped N4 mechanisms versus open acceptance

Codex for Andrew

25 September 2026

Outcome. Six further scheduling-parity ledger entries lagged the production tree. Forward unit continuation, canonical root-mark admission, post-forward caller closure, Eliminate dense entry, and its resolution ceiling are present since `7a668e76`; same-conflict suppression after Reduce is present since `6d235f4a`. The ledger and engineering notes now distinguish *implemented* from *accepted*. No solver, policy, proof, checker, benchmark pin, or configuration changed. The source/test mapping and historical isolated evidence are in the AM441 report under `benchmarks/reports/`.

Evidence and limitation. Current-source Debug job 1723391 passed the focused `forward_unit`, `strengthen`, `scheduling`, and `eliminate_limit` tests. It had passed 186/187 tests when inspected; its last scripted demo was still running. The older isolated composition for the post-forward closure regressed full runtime by 1.176794 times and C by 1.017340 times, so its incorporation in production is emphatically not a performance sign-off. Affected fuzz, reference trajectories, checked cumulative gates, and the full Debug result remain outstanding. All docs checks pass; six existing document-size warnings remain and no compaction was performed.

Next actions. Finish the full Debug and extended paired AES proof checks, close the general H2 no-option checker-state failure and remaining N1–N4/fuzz/benchmark gates, and then issue the final online-learning readiness assessment. The requested 1,166-instance Tier D comparison at 5,000 seconds, 4 CPUs, and 32 GiB on `cpu-dense-hwulab-q` remains after those fixes, not launched by this audit.
