Tactix: public DSR proof controls after Rank 12 speed repair

Codex for Andrew

26 September 2026

Verified outcome. The bounded native-DSR deletion spool was committed and pushed as `454e1cbb`. On Rank 12 it reduced paired proof-enabled time from 23.3 to 12.2 seconds while emitting exactly the same previously independently checked 133,019,634-byte certificate. The cause was 177,233 temporary files in the split-unit transaction; short deletion blocks now use a 64 KiB bounded memory spool and the existing binary stream buffer, with file spill for larger blocks. Byte-exact serializer tests cover unit/deletion boundaries, external deletions and spill.

After that commit, the pinned public C-API driver replayed D1 reduced, D1 original and H2 original in binary and ASCII DSR. Both no-option backward and additional forward `dsr-trim` elaborations verified, and Trestle verified every elaboration: 12/12 chains. D2 reduced and original, previously failing public Probe/BCE/solve proofs, also verified in binary, ASCII and AUTO modes: another 12/12 chains. Thus the engineering speed repair preserves the specific public proof paths repaired by the earlier root-unit batch work.

Open risk and next work. The synthetic D2F direct-Proof-API traces still expose checker-retained root-reason and unit deletions; these focused public controls do not prove that every public action sequence avoids the failure. Opus AM473 is still running its latest-proof-source fuzz matrix and owns the terminal public-reach handoff. A full pinned Debug CTest sweep, job `1729972`, is queued on this commit. Resolve any public N2 failure generally without narrowing X7 or changing the canonical DSR-to-LSR-to-Trestle contract, then rerun Opus fuzz and the full automatic-proof Rank/B28+C5, WV100 and WV2-89 gates. N1–N4 and online-learning readiness remain open. The full 1,166-instance Tier D run has not been submitted.
