Tactix proof and gate checkpoint

Codex for Andrew

25 September 2026

Outcome. The paired AES checker diagnosis is terminal. Both the candidate and parent generated the same 238,948,969-byte native DSR proof on the original Tier-C AES input. Frozen no-option `dsr-trim` elaborated each proof and pinned Trestle independently verified it. The complete checker chains took 5,780 and 5,790 seconds. The previous 4,800-second matched checker deadline explains the two timeouts; it does not turn the frozen 29/30-per-arm Tier-C campaign into a scorable gate. The manifest, exact hashes, and stage results are in the AM443 technical report.

H2. The canonical no-option DSR problem is separate. The public H2 schedule still has a verified checker-visible root mismatch: an implied reason is retained and a later X7 witness maps the forced literal false. A new two-variable checker control demonstrates that this can make a direct SR addition unsound against the retained formula. It also shows why Trestle is indispensable: a backward-only elaboration misleadingly reports an empty proof, and Trestle rejects it. This control does not prove that every possible alternative no-option derivation is impossible. The canonical contract has not changed. The user has been asked to choose whether to continue pursuing a different no-option representation or to audit the implied-unit deletion option as a candidate contract. AM404/407 document why the option requires a full positive and negative audit before any switch.

Coverage and current work. Structural rule checks pass: 30/30 catalog dispositions, synchronized calculus and guide, and 418/418 cited Kissat/CaDiCaL options accounted for. A current direct-emitter inventory maps 57 Kissat and 60 CaDiCaL producer calls to Tactix action families; AM444 records its scope and limits. These checks do not close X7, the winners' general live PB-calculus gap, or N1–N4. The AM442 C online-configuration repair has focused original-CNF proof/model controls; a separate Claude Code owner explicitly using Opus is preparing its affected fuzz campaign. Frozen full Debug job 1723391 still runs its last scripted demo after 186/187 tests passed at this checkpoint.

Next gates. Collect the terminal Debug and Opus owner reports, resolve H2 without reducing legal X7 actions, and independently check all affected proof and model surfaces. Then repeat the combined Rank 1–50, B28+C5, WV100, WV2-89 and N4 reference-parity gates on one accepted pin. Production online learning still requires a shared configurable inprocessing slot controller and owned, safe live switches for branching and complete clause-deletion strategies. The full 1,166-instance Tier D comparison remains deferred until those prior gates and the final readiness review pass.
